Contact List of Key Personnel 38
Map of LLE and Environs 39

This document is intended to give an overview of this experimental campaign. Where information conflicts with experimental configurations submitted by official methods, those configurations take precedence. Contact the principal investigator prior to making any changes in the configuration to accommodate conflicts of information based on this document.

This document was produced by the Los Alamos National Laboratory under the auspices of the United States Department of Energy under contract No. W-7405-ENG-36.

Goals of the Experiments

This run week consists of two experiments using tetrahedral hohlraums as a uniform source of radiation drive. The first two days are devoted to experiments investigating the flow of a shock past a material interface. As part of this experiment, the laser beam pointing will be measured, the SOP will be qualified further, a series of shots with double interfaces will be shot, the SOP and side-on radiography will be compared, and the drive from a tetrahedral hohlraum will be measured.

The third day of this run week is designed to complete the experiments begun in December 1998 on thin-shell Rayleigh-Taylor growth in copper. The run day will include shots to verify laser pointing, diagnostic pointing, modulation transfer function (MTF) measurements at the spatial frequency of interest, and RT experiments. The RT packages are of two types: a package "tamped" by a Be filter, and an "untamped" package where the Be merely filters the drive radiation. These will highlight the differences between the classical and ablatively driven Rayleigh-Taylor instabilities, respectively.

The primary goals of each experiment are summarized as:

Structured Shock

Measure shock propagation
Tetrahedral drive measurements
Further qualify the SOP (Streaked Optical Pyrometer)

Thin Shell Rayleigh-Taylor

Complete data set of nonlinear Rayleigh-Taylor experiments begun in December 1998.

Shot Plan for the Entire Week

Major facility changes:
Day 2: Change timing of 5 backlighter beams
Day 2: Place imaging x-ray streak camera in TIM 4, change pulse shape to PS26
Day 3: Massive repointing and retiming of 21 backlighter beams
Change all TIM diagnostics

	Tuesday, 6/22	Wednesday, 6/23	Thursday, 6/24
	BL: 0.0 and 1.1 ns	BL: 1.1 and 2.2 ns	PS26; Move BL's (21 beams)
1	Pointing - Sphere/SOP Timing	Diag Timing* - SOP Res	Pointing - Sphere

6	Double Interface-T	Double Interface-T	Thin Shell - Fe backlighter
7	Double Interface-U	Double Interface-U	Thin Shell - Fe backlighter
8	Shock Coincidence	Radial Shock Motion	Thin Shell - Fe backlighter
9	Shock Coincidence	Radial Shock Motion*	Thin Shell - Fe backlighter
		PS26; Insert SSC4	
10	Double Interface-T	Side-on Thin Shell	Thin Shell - Fe backlighter
11	Double Interface-U	Side-on Thin Shell	Thin Shell - Fe backlighter
12	Shock Coincidence	Side-on Thin Shell*	Repeat one of above
13	Repeat Double Interface	Repeat Double Interface	
	BL at 0.0 ns: 42, 44, 53, 57, 62	BL at 1.1 ns: 45, 47, 40, 51,	BL 2.5 ns: 13, 18, 32, 59, 68, 69
	BL at 1.1 ns: 45, 47, 40, 51, 69	BL at 2.2 ns: 42, 44, 53, 57	BL 3.9 ns: 11, 14, 24, 47, 66, 67

Note: Foils for SOP timing if needed
***drop as necessary**

June 11, 1999

Structured Shock Experiment – Goals

Principal Investigators: George Kyrala and Steve Batha, LANL P-24
Theory: S. Robert Goldman, LANL XPA

The objectives of the experiments are to study the generation and propagation of shocks through material inhomogeneities involving either structured surfaces or material filled joints. The experiments use shocks generated by radiation drive from tetrahedrally illuminated spherical hohlraums with four laser entrance holes (LEH's). A fifth hole facing the SOP port mounts the package for either face-on or side-on radiography. The SOP will measure the temporal and spatial distribution of the shock breakout at the rear surface of the load. Side-on radiography at the Ti He-like lines will be used to measure both the spatial distribution of the shock front and the density variation across the shock.

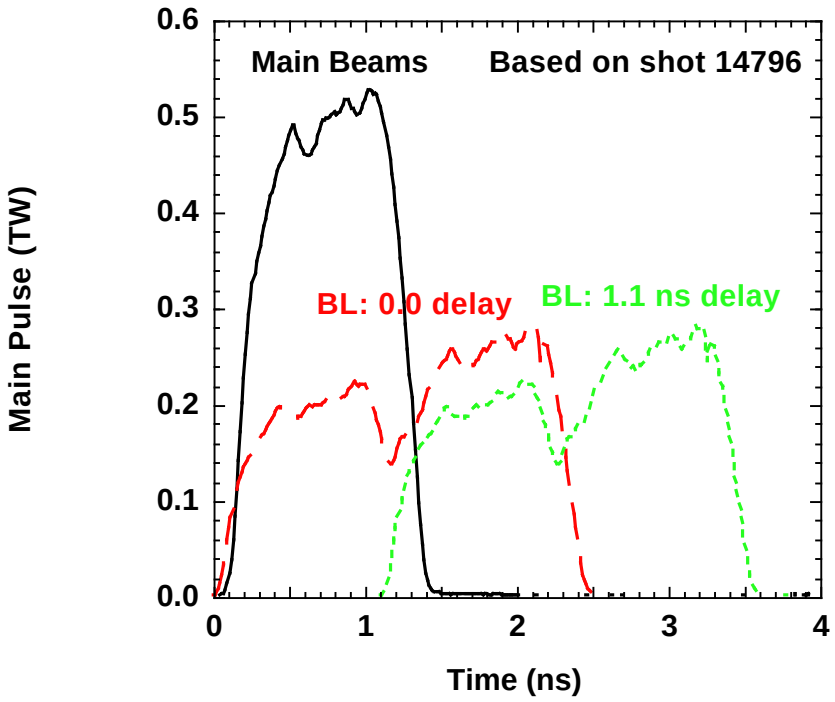
Structured Shock Experiment – Laser Conditions

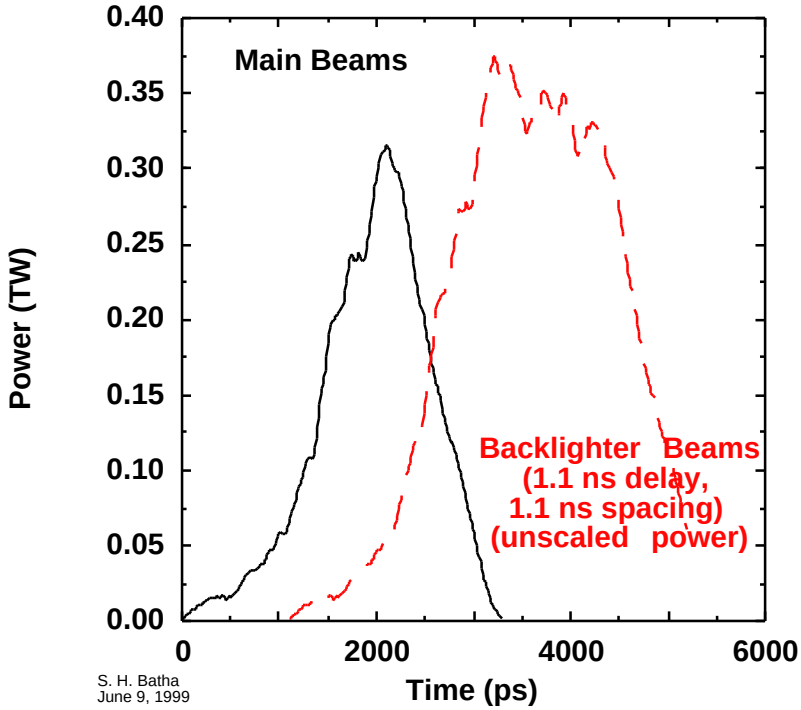
1-ns square pulse (SG1011)
No phase plates
49 drive beams
Max energy for all beams
Tetrahedral hohlraum in H4-H7-H13-H20 configuration
Ti backlighter for side-on radiography facing Port P6
Backlighters in two groups of 5
1.1 ns delay between two groups of backlighters
Package on not directly facing a port – closest is H14 (TIM 5)
One beam is not used

Backlighter beams

Set 1	Day 1 start at 0.0 ns Day 2 start at 2.2 ns	42, 44, 53, 57, 62
Set 2	Days 1 and 2 start at 1.1 ns	45, 47, 40, 51, 69



The backlighter timings for the structured shock experiments. The backlighter timings change between day 1 and day 2.



The Thin-Shell Side-on Radiography shots will use pulse shape 26 with the same backlighter timings as the structured shock experiments.

Thin Shell Rayleigh-Taylor Experiment – Goals

Principal Investigators: Gottfried T. Schappert and Steve Batha, LANL P-24
Theory: Dave Hollowell and Rod Mason, LANL X-Div

The objective of this experiment is to compare the classical material pressure-driven RT instability with the purely ablative-driven RT instability. The experiment compares the RT growth in two types of targets. The tamped packages consist of a copper foil with 45 μm wavelength, 0.5 μm amplitude corrugations on top and is overcoated with a layer of Be. The untamped package consists of the same copper foil with the same Be layer set 200 μm above the copper.

Both packages are mounted on a tetrahedral hohlraum, driven by hohlraum radiation and face-on radiographed using a 6.7 keV iron backlighter. The Cu foil in the tamped package is driven by the Be filtered drive plus the Be material pressure, whereas the untamped package experiences only the Be filtered drive. Hence, the difference in drive is only the material pressure generated from the Be.

Thin Shell Rayleigh-Taylor Experiment – Laser Conditions

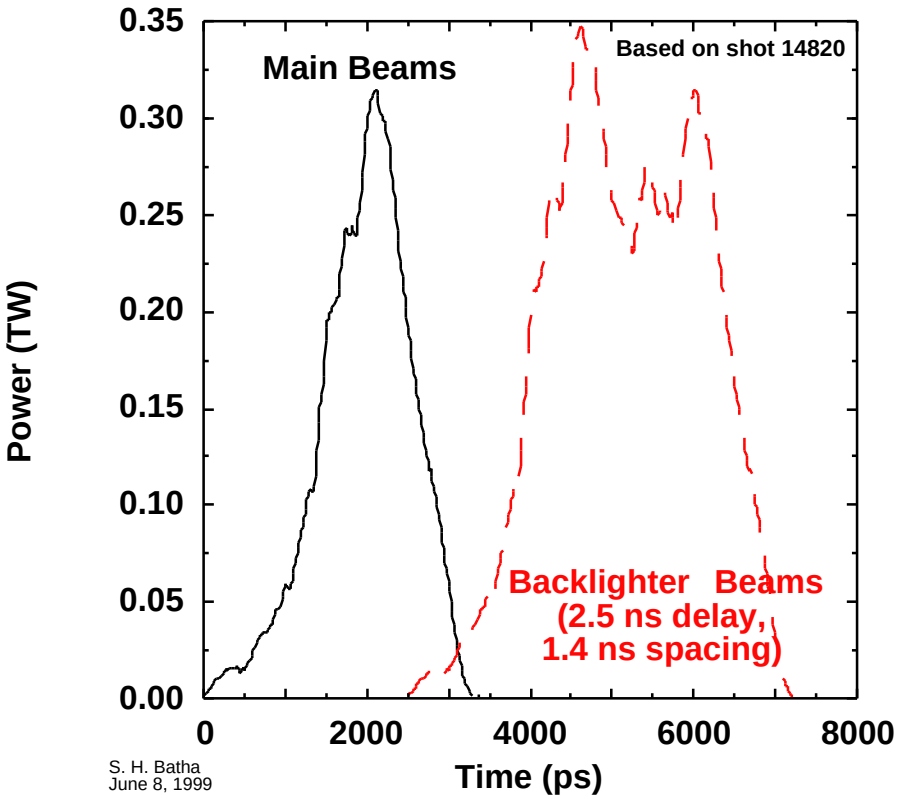
Pulse shape 26
No phase plates
45 drive beams
Max energy for all beams
Tetrahedral hohlraum in H4-H7-H13-H20 configuration
Fe backlighter flush on H7 target LEH
Backlighters in two groups of 6
1.4 ns delay between two groups of backlighters
Package on H14
Three beams are not used

Backlighter beams are 1A and 2B for one and 1B and 2A for the other. Two six-leaf clovers rotated 60 degrees are formed. This pattern will not be smooth with PS26.

Backlighter on H-7 Fe disk
Delay 2 groups of beams relative to each other to produce approx. 3 ns long pulse.
Each beam is PS 26.

Delay 2.5 ns		**Delay 3.9 ns**	
Cone 1A Beams	59	Cone 1B Beams	67
	18		66
	13		24
Cone 2B	69	Cone 2A	47
	68		14
	32		11

Beams 50, 20, and 58 not used



Timing for main pulse and sum of backlighter beams based on December 1998 experience. The Power axis is somewhat arbitrary in this graph.
