ABSTRACT

A single level Breit-Wigner analysis of Pu^{239} is folded into a Maxwell velocity distribution to obtain total, scattering, fission, and radiative capture cross sections versus energy for neutron energies of 0.025 to 43 ev, and for Pu^{239} temperatures of 0.0253 to 50 ev.

ACKNOWLEDGMENTS

This paper could not have been published without the valuable work of D. J. Hughes, J. A. Harvey, R. Carter and associates of the Brookhaven National Laboratory Compilation Center. To them and through them to the nuclear spectroscopists, whose results they compile, we wish to express our sincere thanks. Among the latter, we wish to thank especially Dr. L. M. Bollinger, of Argonne National Laboratory, for his kindness in keeping us informed of his group's work. We wish further to acknowledge the kind help of the IBM 704 operating section of Group T-1, under the direction of Jack Mann; and of Marie Odell, and Mrs. Alice M. Snowden.

I. INTRODUCTION

Because of the narrowness of heavy element neutron resonances and because the Doppler width¹ increases with the neutron energy as well as with the temperature, the effect of temperature may prove to be important in certain reactor designs and elsewhere.

II. METHOD

For computing the nuclear cross sections we have used the isolated level Breit-Wigner formulas.² Because of the narrowness of the levels with respect to their spacing it is evident that interference between levels is small and that therefore the isolated level formulas are appropriate.³ We have, of course, accounted for interference of resonance scattering with potential scattering. Our formulas also allow linear level-level interference in scattering, but no reaction interference. We further take the orbital angular momentum to be 0. The reaction widths are presumed constant with energy, although varying from resonance to resonance.

We presume the target nuclei to have a three-dimensional Maxwellian velocity distribution. The validity of this assumption is discussed by Lamb;⁴ it is apparently a good approximation for temperatures exceeding the Debye temperature of the solid. Our very preliminary studies of special models encourage the use of Maxwellian distributions even below the Debye temperature as a useful approximation.

We correct for the effect of levels not explicitly represented by the introduction of $1/V$ terms and of negative energy resonances. We hold such "adjusting" to a minimum and insist that the parameters of such levels be

-
1. $\Delta \text{Doppler} = 2\sqrt{m_n E_n kT/M_{Pu}}$, H. Bethe, Rev. Mod. Phys. 9, 140 (1937)
 2. Given for example in D. J. Hughes and J. A. Harvey, Brookhaven National Laboratory Report, BNL-325 (1955)
 3. See, for example, T. Teichmann, Phys. Rev. 77, 506 (1950).
 4. W. E. Lamb, Jr., Phys. Rev. 55, 190 (1939); see also I. I. Frenkel, Kinetic Theory of Liquids, Oxford University Press, London, 1946.

reasonable for that isotope on the basis of parameters of other levels of that isotope. Recognizing that with sufficient parameters any curve could be fit as closely as we please, we have perhaps erred on the side of making one negative energy level do the work of many. Such curve fitting is by no means wholly arbitrary, since we require that all the cross sections be matched to the limits of experimental error, spread in points, and resolution. Indeed, the senior author can testify to much tedious work as evidence of the stringency of the above requirements. Further, this fitting is effective only on the cross section at low neutron energies.

For example, in the case of thermal fissioners we require that the entire curve of σ_T vs. E_n and σ_F vs. E_n be followed for a temperature of 0.0253 ev to within experimental error, as well as that the thermal values of $\sigma(n, \gamma)$ and $\bar{\sigma}_S$ be matched. For higher energies we take our parameters direct from experiment and only match curves to the extent of introducing fission widths where the neutron width and position are the only known parameters. We determine such fission widths by insisting that the average fission cross sections match. The fission widths are usually known for the larger levels, so such fission width estimates affect the cross sections in a minor way. Where unknown, the radiation width is taken from an average of the well-known radiation widths of the isotope in question. The constancy of radiation widths has been well established. Following Hughes and Harvey,⁵ we take $g = 1/2$ where unknown. For the purposes of reference, we outline our algebraic manipulations and give our final formulas.

The nuclear Maxwellian velocity was resolved into a component parallel to the neutron velocity and one perpendicular to the neutron velocity. The appropriate Breit-Wigner isolated level sum times the Maxwell distribution was then integrated first over the velocity coordinates perpendicular to the neutron velocity and then over those parallel to it.

For example, the capture cross section versus neutron energy is given by:

$$\sigma_\gamma(E_n) = \int_{-\infty}^{\infty} dV_Z \int_0^{\infty} dV_\rho \left(\frac{M}{2\pi kT} \right)^{3/2} e^{-\frac{M}{2kT} (V_Z^2 + V_\rho^2)} \cdot \left[\sigma_{\gamma \text{tot}} \sqrt{\frac{E_{\text{tot}}}{E}} + \sum_{i=1}^N \sigma_{\gamma^i}^i(E) \right] dV_Z 2\pi V_\rho dV_\rho$$

5. D. J. Hughes and J. A. Harvey, op. cit.

where the symbols have the following meanings:

σ_γ is capture cross section.

σ_γ^i is isolated level Breit-Wigner capture cross section.

σ_{tot} is the thermal $1/V$ contribution to the capture cross section.

E_n is the neutron energy (lab. system).

E is the relative neutron energy $= \frac{1}{2} \left(\frac{mM}{m+M} \right) \left[V_p^2 + \left(\sqrt{\frac{2E_n}{m}} + V_Z \right)^2 \right]$

V_Z is the laboratory nucleus velocity \parallel neutron direction,

V_p , the same but \perp .

M is the mass of the nucleus.

E_{ot} = 0.0253 ev.

Changing the variables from V_Z and V_p to E and V_Z and inverting the order of integration will give:

$$\sigma_a(E_n) = \frac{0.564317B^2}{A} e^{-A^2} \int_0^\infty dx \left\{ \left(e^{2ABx} - e^{-2ABx} \right) e^{-B^2 x^2} \cdot \left[0.15906\sigma_{a\text{ot}} + 6.50938 \cdot 10^5 g \sum_{i=1}^N \frac{\left(\Gamma_n^i \Gamma_a^i / \sqrt{E_i} \right)}{\left(x^2 - E_i \right)^2 + \frac{1}{4} \left(\sqrt{\frac{x}{E_i}} \Gamma_n^i + \Gamma_a^i \right)^2} \right] \right\}$$

$$\sigma_s(E_n) = 4\pi(1-g) \left(\frac{R}{10} \right)^2 + \frac{3.5449gB^2}{A} \int_0^\infty d(x^2) \left\{ \left(e^{2ABx} - e^{-2ABx} \right) e^{-B^2 x^2 - A^2} \cdot \left| \sum_{i=1}^N \frac{227.596 \frac{\Gamma_n^i}{\sqrt{E_i}}}{\left(x^2 - E_i \right) + \frac{j}{2} \left(\sqrt{\frac{x^2}{E_i}} \Gamma_n^i + \Gamma_a^i \right)} + \frac{R}{10} \right|^2 \right\}$$

where

$$j \equiv \sqrt{-1}$$

$$A \equiv \sqrt{\frac{ME_n}{mT}}$$

$$B \equiv \sqrt{\frac{M+m}{mT}}$$

$$g = \frac{1}{2} \left(\frac{2J+1}{2I+1} \right)$$

$$J = I \pm \frac{1}{2} \text{ for } l = 0 \text{ neutrons}$$

I is spin of target

N is the number of levels

with m and M the masses of the neutron and nucleus, respectively, in the same units.

a is absorption. The fission and radiation widths were obtained by replacing Γ_a by Γ_f and Γ_γ in the numerators.

S is elastic scattering.

E_n is the laboratory neutron energy in electron volts.

σ_{aot} is the appropriate 1/V contribution at 0.0253 ev.

R is the effective nuclear radius in fermis (10^{-13} cm).

T is the temperature in electron volts.

For each resonance i, E_i is its location in the relative system (i.e., compound nucleus), Γ_n^i , its neutron width, Γ_f^i , its fission width, Γ_γ^i , its radiative capture width, and $\Gamma_a^i = \Gamma_f^i + \Gamma_\gamma^i$, its absorption width.

These integrals were computed numerically on the IBM 704.

III. SOURCES

The level parameters were obtained from a private communication with D. J. Hughes⁶ and are the same as those in BNL-325, Supplement 1. The thermal values and the low energy cross sections were taken from BNL-325 and the Geneva Addendum. The BNL-325 value of σ_γ , 315 barns, leads to a 10% too high value of α , the capture to fission ratio at thermal, according

-
6. These parameters appear in "Neutron Cross Sections," by D. J. Hughes and R. B. Schwartz, BNL-325, Supplement 1, Brookhaven (Jan., 1957). We are also indebted to Dr. L. M. Bollinger of Argonne National Laboratory for a communication of the preliminary results of Bollinger, Côté, LeBlanc, and Thomas (1956).

to Supplement 1, BNL-325. We are otherwise roughly within the scatter of points of α in BNL-325, Supplement 1, in the regions plotted.

We found it almost possible to account for negative energy level effects with only one level. However, the departure from experiment, although small, was definite and we were forced to use two levels and a $1/V$ part to fit the curves. Such levels enabled good agreement everywhere but at the valley between resonances, located at about 9.0 ev. There we were slightly but definitely high. This could easily be cured by postulating many small resonances in the region 1 to 6 ev in place of the one large negative energy resonance. However, the introduction of multiple resonances without experimental justification is dangerously close to the philosophy of adding parameters in order to fit data; the more parameters the more data can thus be fit. We therefore decided that this discrepancy should be represented as evidence of a failure of the isolated level approximation. We hasten to add that the failure is negligible because (1) the discrepancy is itself small and (2) it occurs in a small part of the cross section. We therefore proceeded to assume reaction destructive interference between the adjacent levels of sufficient intensity to bring the total cross section below that of experiment (below to allow for slight instrument resolution).

Our level parameters are thus (lab. system)

i	E_i (ev)	Γ_{γ}^i (mv)	Γ_f^i (mv)	Γ_n^i (mv)

g is $1/2$; R is 8.6×10^{-13} cm; the fission $1/V$ part is 25 barns at 0.0253 ev; the capture $1/V$ part is 0.

IV. RESULTS

The results for Pu^{239} are presented in Tables I — XI. The temperatures, T , range by factors of 2 roughly from 0.0253 to 50 ev. The neutron energy range is decreased for high T , since more levels can contribute to a given energy and thus end points are not meaningful.

A few graphs are plotted (Figs. 1 — 6) to give the reader a feel for the effect of temperature. Further, σ vs. E_n at $T = 0.0253$ ev is plotted, since, to our knowledge, that curve has not yet been given. The errors of the 0.0253 ev curves are presumably of the order of existing experiment. The capture cross section has, in addition, the assumption of constant capture widths. A more serious cause of error in the case of the capture cross section may lie at lower energies where a very poor choice of negative level parameters can lead to a possibly large even though second order error in the capture cross section. The accuracy of the isolated level approximation can be estimated from the level widths and spacings.³ Such a calculation for Pu^{239} indicates that appreciable interference is not to be expected until a resonance has dropped to 0.1% or less, on the average, of its peak value. One finds for an even-even isotope like U^{238} a corresponding figure of 10^{-5} of peak value. It should be noted that the Doppler broadening of levels is incoherent and therefore cannot increase interference. In fact, thermal motion masks the minimum, where interference first appears, with contributions from the dominant, relatively unaffected maxima. Moreover, levels interfere only if they are from the same compound state; the average upper bound to the probability of level-level interference is therefore further reduced in the case of Pu^{239} (spin 1/2) to the order of 0.05% of peak value for compound spin 1 and to the order of 0.01% of peak value for compound spin 0.

V. FUTURE WORK

We have completed a similar study of U^{238} and U^{235} which we plan to re-do using the later data of Supplement 1, BNL-325. Studies of other isotopes can be undertaken as indicated by demand. Provided a region above, say, 1 ev only is desired, it is possible for us to give the results in a day or two. Estimating the negative energy level parameters by curve-fitting is more time-consuming.
