## ANALYZING WIPE TESTS USING A LUDLUM SURVEY METER WITH MODEL 44-88 \& 44-9 PANCAKE GM PROBES

## NORTHEASTERN UNIVERSITY RADIATION SAFETY PROGRAM

Note: Model 44-7 end window GM probes should not be used to analyze wipes

1. Wipe the area using a 1" diameter filter paper. For flat areas such as work-benches and floors, the surface area per wipe should be $100 \mathrm{~cm}^{2}$ (approximately 4 inches by 4 inches).

2a. Turn on the survey meter and perform a battery check. b. If the probe has a plastic cap/cover, REMOVE it. Flip the F/S response switch to 'S' (Slow response), and hold the probe against the check-source epoxied to the side of the meter. Ensure that you can reproduce its expected reading (noted on the yellow calibration sticker), at the appropriate multiplier position. Do NOT use the survey meter if you cannot reproduce the check source reading within $10 \%$, or if the meter is past its calibration date (also written on the calibration sticker).
3. Place the GM pancake probe on a flat, low-background surface (preferably a clean lead brick; covered with duct-tape or equivalent to minimize the risk of lead poisoning). Turn the thumb switch to multiplier x0.1. Observe the reading over a 30 second interval. This is the BACKGROUND radiation reading, typically around $0.02 \mathrm{mR} / \mathrm{h}$, or approximately 70 CPM (counts per minute).
4. Lay the wipe (dirty side up) flat on the lead brick. Place the GM pancake probe over the wipe, such that the frame of the probe rests directly on the lead brick. Make sure the wipe does not touch any part of the probe, to avoid contaminating it. Observe the reading as in the previous step. This is the GROSS reading.
5. Subtract the Background reading from the gross reading to get the NET reading in $\mathrm{mR} / \mathrm{h}$. Use Table-1 below to convert $\mathrm{mR} / \mathrm{h}$ to CPM, and vice-versa.
6. Divide net CPM by efficiency (Table-2) to obtain DPM (disintegrations per minute). Note that these efficiencies are applicable only to the counting geometry described above. Routine area wipe tests are reported as DPM/100 $\mathrm{cm}^{2}$. If a wipe test reveals contamination exceeding $200 \mathrm{DPM} / 100 \mathrm{~cm}^{2}$, decontaminate the area and

| $\begin{array}{r} \mathrm{mR} / \mathrm{h} \\ \times 0.1 \mathrm{sca} \end{array}$ | CPM* | $\begin{array}{r} \mathrm{mR} / \mathrm{h} \\ \times 1 \mathrm{sc} \end{array}$ | CPM | $\begin{array}{r} \mathrm{mR} / \mathrm{h} \\ \times 10 \mathrm{sc} \end{array}$ | CPM |

| ${ }^{35} \mathrm{~S},{ }^{14} \mathrm{C}$ | $7.5 \%$ | $\mathbf{0 . 0 7 5}$ |

Table-2. Pancake GM probe efficiencies
for counting wipe tests
EXAMPLE 1- ${ }^{32} \mathrm{P}$ work-area wiped over $100 \mathrm{~cm}^{2}$ : Bkg = 70 CPM; Gross $=0.04 \mathrm{mR} / \mathrm{h}$ ( 130 CPM ) Net $=130-70=60 \mathrm{CPM}$ Conversion: $60 / 0.15=\underline{400 \mathrm{DPM} / 100 \mathrm{~cm}^{2}}$

EXAMPLE 2- ${ }^{14} \mathrm{C}$ contaminated glassware: Bkg $=70$ CPM; Gross $=0.07 \mathrm{mR} / \mathrm{h}$ ( 230 CPM ) Net = 230-70 = 160 CPM
Conversion: 160 / 0.075 = 2133 DPM

Table-1. Conversion between $\mathrm{mR} / \mathrm{h}$ and CPM for Ludlum survey meters
test again.
